Carbon accounting methods

Globally, carbon accounting follows two methods which have different 'system boundaries'

- Intergovernmental Panel on Climate Change (IPCC)
 - Used for national inventory
- Life Cycle Assessment (LCA)
 - Used to calculate embedded carbon emissions in products i.e. kg CO₂ eq per kg of grain, meat or milk

Carbon accounting calculations

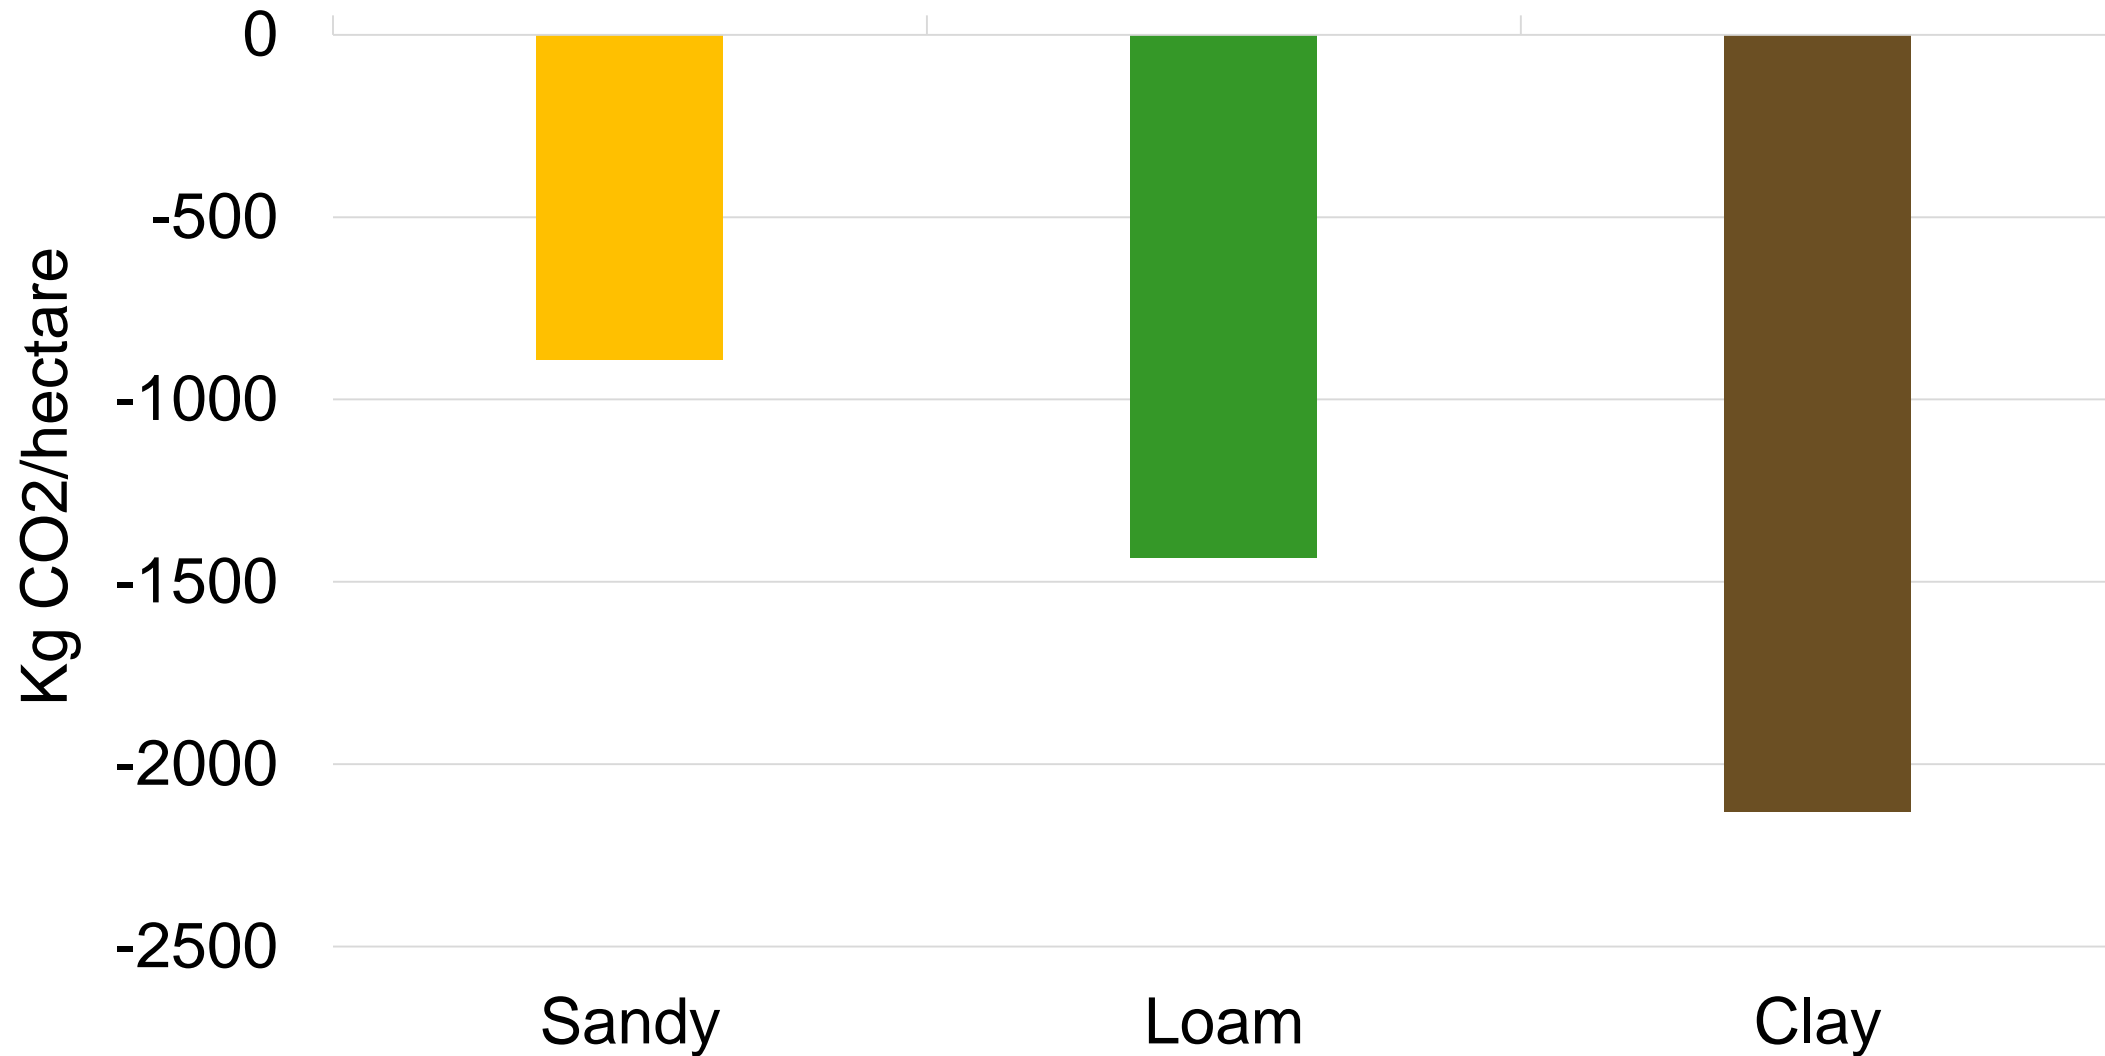

Both Carbon accounting methods require:

- Activity data
 - e.g fertiliser type and amount, cultivation methods
- Emissions factors
 - Tier 1 – international default figure
 - Tier 2 – national figures
 - Tier 3 – Values dependant on circumstances (e.g different figures for different soil types)

On-farm nitrous oxide emissions factors

Selected Source	Emission factor used	Tier 1 factor
Chemical N application		
• CAN, NPK, Other	0.35% N	1.0% N
• Urea	0.27% N	1.0% N
• Protected Urea	0.20% N	1.0% N
Crop Residues	0.60% N	0.60% N
Organic materials application	0.60% x (organic N)	0.60% x (organic N)

Straw incorporation & carbon sequestration

*Van Groenigen et al. 2011 – Straw yield, 4 t/ha

Carbon footprint of crop production

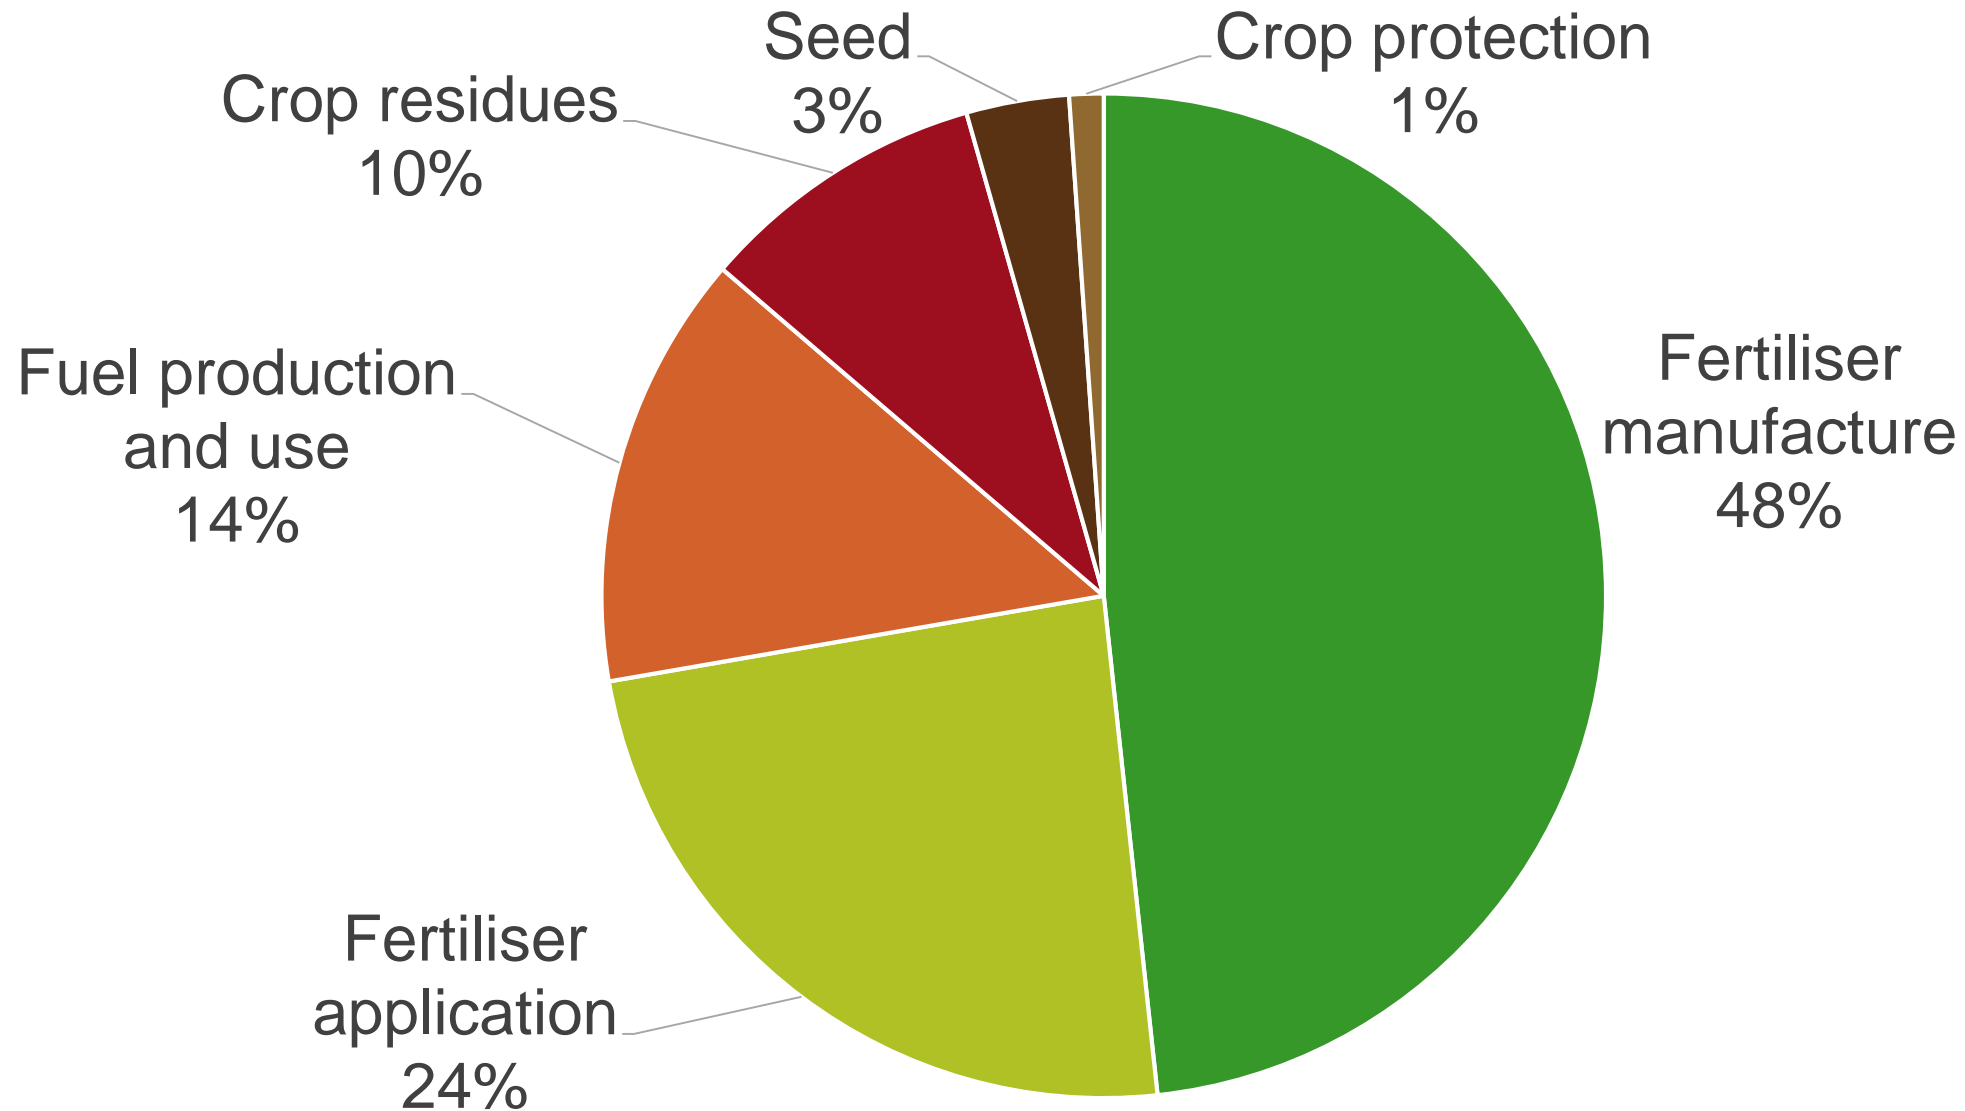

Oak Park, Knockbeg

What is the C footprint of each crop in rotation?

What contributes to the carbon footprint of winter wheat ?

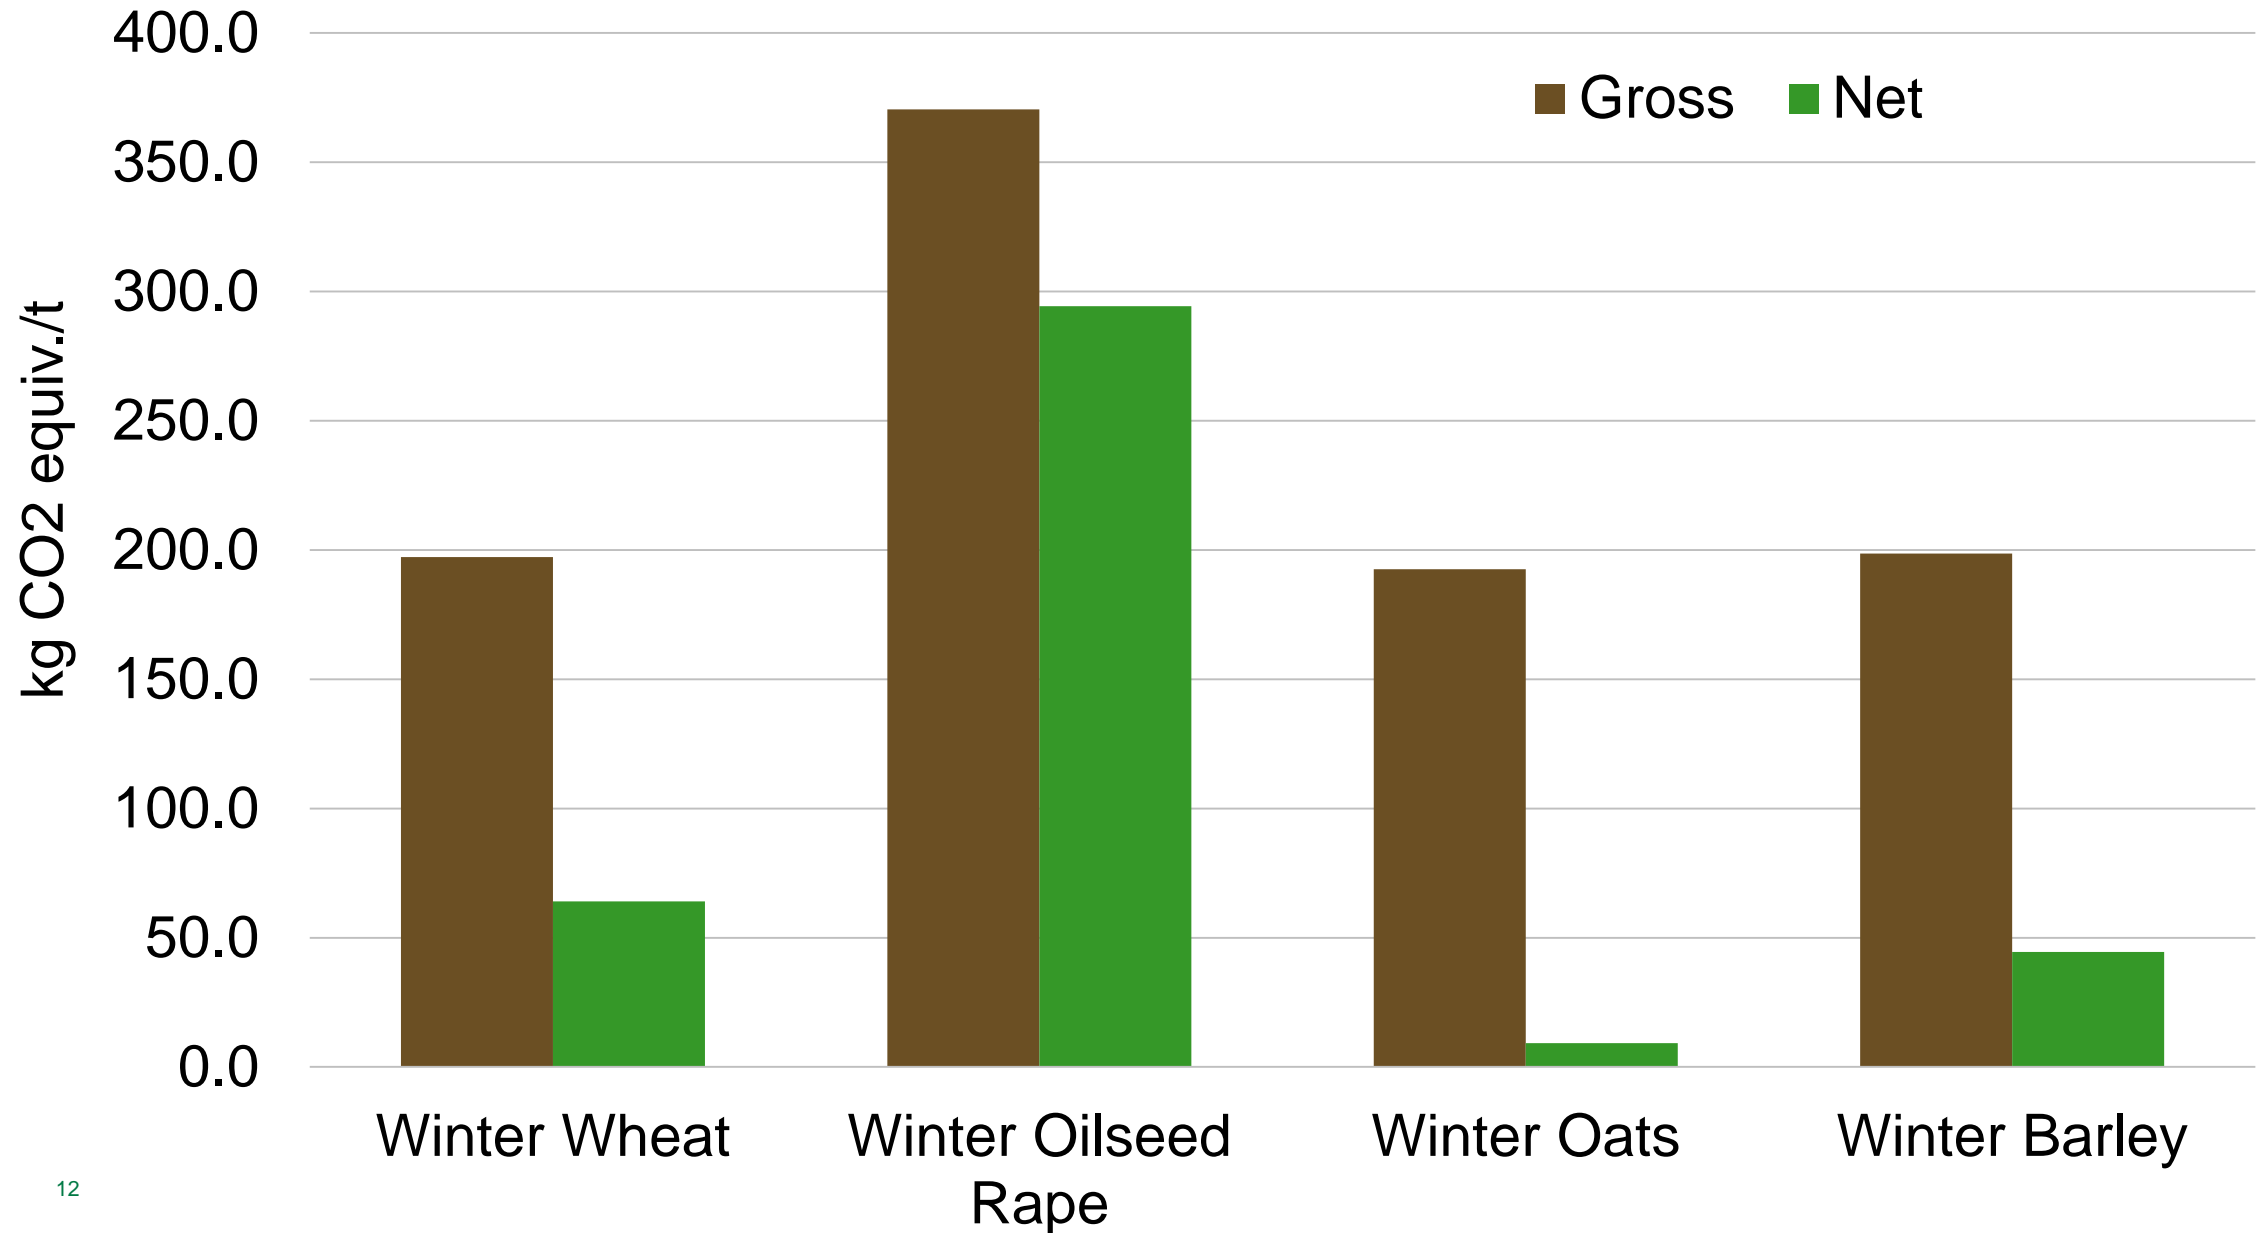

Influence of cultivation method on carbon footprint ?

Straw incorporation: C sequestration rate per crop ?

Straw incorporation: C footprint of crops ?

Conclusions

- N fertiliser use and yield main factors affecting Carbon Footprint
- Further research needed to refine some emissions factors
- Carbon footprint of Irish grain is low by international standards
- Endorsement of the sector's credentials to stakeholders in the value chain
